

10. Comparison of a non-crossover R<sup>g</sup> mutant with a crossover R<sup>g</sup> mutant.\*

\* This report represents work done jointly by the late L. J. Stadler and myself.

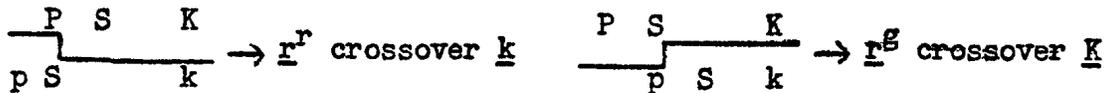

Accumulating evidence suggests that mutations at the R<sup>r</sup> locus yield non-crossover R<sup>g</sup> mutants of constitution (pS) as well as crossover R<sup>g</sup> mutants. A previous paper (Genetics 1956) presents data indicating that an R<sup>g</sup> allele, designated R<sup>g</sup>-14, is deficient for element (p). This type is expected to arise as the result of the occurrence of unequal crossing-over in the parent allele. However, R<sup>g</sup>-14 was derived from a stock without genetic marking to the left or right of the R<sup>r</sup> locus, and thus it could not be proved to be due to unequal crossing-over.

A more critical study to investigate the possibility of these two types of plant-color mutants is now being conducted with several R<sup>g</sup> alleles of known crossover and non-crossover origin. This report summarizes the data from R<sup>g</sup> non-crossover-1 (designated R<sup>g</sup> nco-1) and R<sup>g</sup> crossover-1 (designated R<sup>g</sup> co-1).

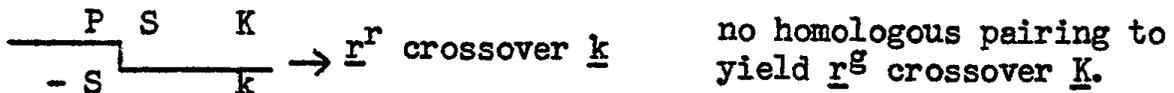

In the case of the compound R<sup>g</sup> nco-1 k/R<sup>r</sup> K, the expected types of unequal crossovers (seed-color) would include the apparent mutants r<sup>r</sup> k and r<sup>g</sup> K, assuming that R<sup>g</sup> nco-1 is (pS). The R<sup>g</sup> co-1 k/R<sup>r</sup> K compound, on the other hand, should yield only r<sup>r</sup> k unequal cross-overs, if it lacks the (p) element.

These expected types of unequal crossovers are illustrated in the following diagrams:

A. Non-crossover Mutant (pS)

B. Crossover Mutant (- S)

The data from the non-crossover R<sup>g</sup> mutant come from two cultures in which the knob-10 linkage is different. In the case of the R<sup>g</sup> nco-1 k/R<sup>r</sup> K compound, the expected types of unequal crossovers would be r<sup>r</sup> k and r<sup>g</sup> K. The R<sup>g</sup> nco-1 K/R<sup>r</sup> k culture, which is the less desirable one since the r<sup>g</sup> crossovers would be knobless and thus uncommon, should produce r<sup>r</sup> K and r<sup>g</sup> k crossovers. The results are as follows:

Culture	Pop.	Mutants	r <sup>g</sup> co K	r <sup>r</sup> co k	r <sup>g</sup> nco k	r <sup>r</sup> nco K	Deficiency
A. R <sup>g</sup> nco-1 k/R <sup>r</sup> K	89,550	24	10	5	4	3	2
			<u>r<sup>g</sup> co k</u>	<u>r<sup>r</sup> co K</u>	<u>r<sup>g</sup> nco K</u>	<u>r<sup>r</sup> nco k</u>	

B. R<sup>g</sup> nco-1 K/R<sup>r</sup> k      86,217   15      3      4      4      4      0

In culture A, with R<sup>g</sup> nco-1 k, 24 colorless seeds were found, and of these 15 were unequal crossovers, 7 were non-crossovers, and 2 were R deficiencies. Of the 15 crossovers identified, 10 were of type r<sup>g</sup> K, the critical class which carries (p), and 5 were of type r<sup>r</sup> k.

In culture B, the R<sup>g</sup> nco-1 K/R<sup>r</sup> k compound yielded 7 unequal crossovers and 8 non-crossovers. Of the 7 crossovers produced, 3 were r<sup>g</sup> k and 4 were r<sup>r</sup> K. The non-crossovers included 4 r<sup>g</sup> K and 4 r<sup>r</sup> k.

Thus the occurrence of 13 r<sup>g</sup> crossovers indicates that change of R<sup>r</sup> to R<sup>g</sup> occurred by a recessive mutation of element (P) rather than by physical loss of this element.

The results of the type and frequency of unequal crossovers produced in cultures heterozygous for R<sup>g</sup> co-1 are summarized in the following table:

Culture	Pop.	Mutants	r <sup>g</sup> co K	r <sup>r</sup> co k	r <sup>g</sup> nco k	r <sup>r</sup> nco K	Deficiency
R <sup>g</sup> co-1 k/R <sup>r</sup> K	102,020	46	0	24	5	13	4

A striking difference appeared in the type of unequal crossovers produced from R<sup>g</sup> co-1 k/R<sup>r</sup> K as compared to those from R<sup>g</sup> nco-1. Out of 24 crossovers found, all were of the r<sup>r</sup> k class with none of the r<sup>g</sup> K crossover type. Approximately 17 of these 24 crossovers should have been r<sup>g</sup> K, assuming a 70% selective advantage of the knob bearing chromosome. In addition, 18 non-crossovers were recovered, of which 13 were r<sup>r</sup> K and 5 were r<sup>g</sup> k.

These results indicate that the apparent mutation of R<sup>r</sup> to R<sup>g</sup> involved the loss of element (p).

It is also of interest to note that the frequency of unequal crossovers in the R<sup>g</sup> co-1 heterozygote, resulting only from proximal displacement of (S), is greater than the frequency of unequal crossovers in R<sup>g</sup> nco-1/R<sup>r</sup> from both proximal and distal displacement of (S). Out of 37 seed-color mutants analyzed from R<sup>g</sup> nco-1 (two mutants were excluded since they are deficiencies), 22, or 59%, were unequal crossovers. In the case of R<sup>g</sup> co-1, 24 of the 42 mutants, or 57%, were crossovers. Previous evidence from R<sup>g</sup>-14, which is presumably (S) in constitution, also showed this increased frequency of unequal crossing-over. If this difference proves to be regular among known crossover R<sup>g</sup> alleles, it may be used as another criterion to distinguish crossovers from non-crossover R<sup>g</sup> mutants.
